### General Description

MIC4420, MIC4429 and MIC429 MOSFET drivers are tough, efficient, and easy to use. The MIC4429 and MIC429 are inverting drivers, while the MIC4420 is a non-inverting driver.

They are capable of 6A (peak) output and can drive the largest MOSFETs with an improved safe operating margin. The MIC4420/4429/429 accepts any logic input from 2.4V to  $V_S$  without external speed-up capacitors or resistor networks. Proprietary circuits allow the input to swing negative by as much as 5V without damaging the part. Additional circuits protect against damage from electrostatic discharge.

MIC4420/4429/429 drivers can replace three or more discrete components, reducing PCB area requirements, simplifying product design, and reducing assembly cost.

Modern BiCMOS/DMOS construction guarantees freedom from latch-up. The rail-to-rail swing capability insures adequate gate voltage to the MOSFET during power up/down sequencing.

### Features

- CMOS Construction
- Latch-Up Protected: Will Withstand >500mA Reverse Output Current
- Logic Input Withstands Negative Swing of Up to 5V
- Matched Rise and Fall Times ..... 25ns
- High Peak Output Current ..... 6A Peak
- Wide Operating Range ..... 4.5V to 18V
- High Capacitive Load Drive ..... 10,000pF
- Low Delay Time ..... 55ns Typ
- Logic High Input for Any Voltage From 2.4V to  $V_S$
- Low Equivalent Input Capacitance (typ) ..... 6pF
- Low Supply Current ..... 450 $\mu$ A With Logic 1 Input
- Low Output Impedance ..... 2.5 $\Omega$
- Output Voltage Swing Within 25mV of Ground or  $V_S$

### Applications

- Switch Mode Power Supplies
- Motor Controls
- Pulse Transformer Driver
- Class-D Switching Amplifiers

### Functional Diagram

## Ordering Information

Part No.	Temperature Range	Package	Configuration
MIC4420CN	0°C to +70°C	8-Pin PDIP	Non-Inverting
MIC4420BN	-40°C to +85°C	8-Pin PDIP	Non-Inverting
MIC4420CM	0°C to +70°C	8-Pin SOIC	Non-Inverting
MIC4420BM	-40°C to +85°C	8-Pin SOIC	Non-Inverting
MIC4420BMM	-40°C to +85°C	8-Pin MSOP	Non-Inverting
MIC4420CT	0°C to +70°C	5-Pin TO-220	Non-Inverting
MIC4429CN	0°C to +70°C	8-Pin PDIP	Inverting
MIC4429BN	-40°C to +85°C	8-Pin PDIP	Inverting
MIC4429CM	0°C to +70°C	8-Pin SOIC	Inverting
MIC4429BM	-40°C to +85°C	8-Pin SOIC	Inverting
MIC4429BMM	-40°C to +85°C	8-Pin MSOP	Inverting
MIC4429CT	0°C to +70°C	5-Pin TO-220	Inverting

## Pin Configurations

Plastic DIP (N)  
SOIC (M)  
MSOP (MM)

TO-220-5 (T)

## Pin Description

Pin Number TO-220-5	Pin Number DIP, SOIC, MSOP	Pin Name	Pin Function
1	2	IN	Control Input
2, 4	4, 5	GND	Ground: Duplicate pins must be externally connected together.
3, TAB	1, 8	V <sub>S</sub>	Supply Input: Duplicate pins must be externally connected together.
5	6, 7	OUT	Output: Duplicate pins must be externally connected together.
	3	NC	Not connected.

**Absolute Maximum Ratings** (Notes 1, 2 and 3)

Supply Voltage .....	20V
Input Voltage .....	$V_S + 0.3V$ to GND – 5V
Input Current ( $V_{IN} > V_S$ ) .....	50mA
Power Dissipation, $T_A \leq 25^\circ\text{C}$	
PDIP .....	960W
SOIC .....	1040mW
5-Pin TO-220 .....	2W
Power Dissipation, $T_C \leq 25^\circ\text{C}$	
5-Pin TO-220 .....	12.5W
Derating Factors (to Ambient)	
PDIP .....	7.7mW/ $^\circ\text{C}$
SOIC .....	8.3mW/ $^\circ\text{C}$
5-Pin TO-220 .....	17mW/ $^\circ\text{C}$
Storage Temperature .....	$-65^\circ\text{C}$ to $+150^\circ\text{C}$
Lead Temperature (10 sec.) .....	$300^\circ\text{C}$

**Operating Ratings**

Junction Temperature .....	$150^\circ\text{C}$
Ambient Temperature	
C Version .....	$0^\circ\text{C}$ to $+70^\circ\text{C}$
B Version .....	$-40^\circ\text{C}$ to $+85^\circ\text{C}$
Package Thermal Resistance	
5-pin TO-220 ( $\theta_{JC}$ ) .....	$10^\circ\text{C/W}$
8-pin MSOP ( $\theta_{JA}$ ) .....	$250^\circ\text{C/W}$

**Electrical Characteristics:** ( $T_A = 25^\circ\text{C}$  with  $4.5V \leq V_S \leq 18V$  unless otherwise specified.)

# Typical Characteristic Curves

Typical Characteristic Curves (Cont.)

## Input Stage

The input voltage level of the 4429 changes the quiescent supply current. The N channel MOSFET input stage transistor drives a 450 $\mu$ A current source load. With a logic "1" input, the maximum quiescent supply current is 450 $\mu$ A. Logic "0" input level signals reduce quiescent current to 55 $\mu$ A maximum.

The MIC4420/4429 input is designed to provide 300mV of hysteresis. This provides clean transitions, reduces noise sensitivity, and minimizes output stage current spiking when changing states. Input voltage threshold level is approximately 1.5V, making the device TTL compatible over the 4.5V to 18V operating supply voltage range. Input current is less than 10 $\mu$ A over this range.

The MIC4429 can be directly driven by the TL494, SG1526/1527, SG1524, TSC170, MIC38HC42 and similar switch mode power supply integrated circuits. By offloading the power-driving duties to the MIC4420/4429, the power supply controller can operate at lower dissipation. This can improve performance and reliability.

The input can be greater than the +V<sub>S</sub> supply, however, current will flow into the input lead. The propagation delay for T<sub>D2</sub> will increase to as much as 400ns at room temperature. The input currents can be as high as 30mA p-p (6.4mA<sub>RMS</sub>) with the input, 6 V greater than the supply voltage. No damage will occur to MIC4420/4429 however, and it will not latch.

The input appears as a 7pF capacitance, and does not change even if the input is driven from an AC source. Care should be taken so that the input does not go more than 5 volts below the negative rail.

## Power Dissipation

CMOS circuits usually permit the user to ignore power dissipation. Logic families such as 4000 and 74C have outputs which can only supply a few milliamperes of current, and even shorting outputs to ground will not force enough

current to destroy the device. The MIC4420/4429 on the other hand, can source or sink several amperes and drive large capacitive loads at high frequency. The package power dissipation limit can easily be exceeded. Therefore, some attention should be given to power dissipation when driving low impedance loads and/or operating at high frequency.

The supply current vs frequency and supply current vs capacitive load characteristic curves aid in determining power dissipation calculations. Table 1 lists the maximum safe operating frequency for several power supply voltages when driving a 2500pF load. More accurate power dissipation figures can be obtained by summing the three dissipation sources.

Given the power dissipation in the device, and the thermal resistance of the package, junction operating temperature for any ambient is easy to calculate. For example, the thermal resistance of the 8-pin MSOP package, from the data sheet, is 250°C/W. In a 25°C ambient, then, using a maximum junction temperature of 150°C, this package will dissipate 500mW.

Accurate power dissipation numbers can be obtained by summing the three sources of power dissipation in the device:

- Load Power Dissipation (P<sub>L</sub>)
- Quiescent power dissipation (P<sub>Q</sub>)
- Transition power dissipation (P<sub>T</sub>)

Calculation of load power dissipation differs depending on whether the load is capacitive, resistive or inductive.

### Resistive Load Power Dissipation

Dissipation caused by a resistive load can be calculated as:

$$P_L = I^2 R_O D$$

where:

- I = the current drawn by the load
- R<sub>O</sub> = the output resistance of the driver when the output is high, at the power supply voltage used. (See data sheet)
- D = fraction of time the load is conducting (duty cycle)

**Table 1: MIC4429 Maximum Operating Frequency**

V <sub>S</sub>	Max Frequency
18V	500kHz
15V	700kHz
10V	1.6MHz

Conditions: 1. DIP Package ( $\theta_{JA} = 130^\circ\text{C/W}$ )  
 2. T<sub>A</sub> = 25°C  
 3. C<sub>L</sub> = 2500pF

**Figure 3. Switching Time Degradation Due to Negative Feedback**

### Capacitive Load Power Dissipation

Dissipation caused by a capacitive load is simply the energy placed in, or removed from, the load capacitance by the driver. The energy stored in a capacitor is described by the equation:

$$E = 1/2 C V^2$$

As this energy is lost in the driver each time the load is charged or discharged, for power dissipation calculations the 1/2 is removed. This equation also shows that it is good practice not to place more voltage on the capacitor than is necessary, as dissipation increases as the square of the voltage applied to the capacitor. For a driver with a capacitive load:

$$P_L = f C (V_S)^2$$

where:

- f = Operating Frequency
- C = Load Capacitance
- V<sub>S</sub> = Driver Supply Voltage

### Inductive Load Power Dissipation

For inductive loads the situation is more complicated. For the part of the cycle in which the driver is actively forcing current into the inductor, the situation is the same as it is in the resistive case:

$$P_{L1} = I^2 R_O D$$

However, in this instance the R<sub>O</sub> required may be either the on resistance of the driver when its output is in the high state, or its on resistance when the driver is in the low state, depending on how the inductor is connected, and this is still only half the story. For the part of the cycle when the inductor is forcing current through the driver, dissipation is best described as

$$P_{L2} = I V_D (1-D)$$

where V<sub>D</sub> is the forward drop of the clamp diode in the driver (generally around 0.7V). The two parts of the load dissipation must be summed in to produce P<sub>L</sub>

$$P_L = P_{L1} + P_{L2}$$

### Quiescent Power Dissipation

Quiescent power dissipation (P<sub>Q</sub>, as described in the input section) depends on whether the input is high or low. A low input will result in a maximum current drain (per driver) of ≤0.2mA; a logic high will result in a current drain of ≤2.0mA. Quiescent power can therefore be found from:

$$P_Q = V_S [D I_H + (1-D) I_L]$$

where:

- I<sub>H</sub> = quiescent current with input high
- I<sub>L</sub> = quiescent current with input low
- D = fraction of time input is high (duty cycle)
- V<sub>S</sub> = power supply voltage

### Transition Power Dissipation

Transition power is dissipated in the driver each time its output changes state, because during the transition, for a very brief interval, both the N- and P-channel MOSFETs in the output totem-pole are ON simultaneously, and a current is conducted through them from V<sup>+</sup><sub>S</sub> to ground. The transition power dissipation is approximately:

$$P_T = 2 f V_S (A \cdot s)$$

where (A·s) is a time-current factor derived from the typical characteristic curves.

Total power (P<sub>D</sub>) then, as previously described is:

$$P_D = P_L + P_Q + P_T$$

### Definitions

- C<sub>L</sub> = Load Capacitance in Farads.
- D = Duty Cycle expressed as the fraction of time the input to the driver is high.
- f = Operating Frequency of the driver in Hertz
- I<sub>H</sub> = Power supply current drawn by a driver when both inputs are high and neither output is loaded.
- I<sub>L</sub> = Power supply current drawn by a driver when both inputs are low and neither output is loaded.
- I<sub>D</sub> = Output current from a driver in Amps.
- P<sub>D</sub> = Total power dissipated in a driver in Watts.
- P<sub>L</sub> = Power dissipated in the driver due to the driver's load in Watts.
- P<sub>Q</sub> = Power dissipated in a quiescent driver in Watts.
- P<sub>T</sub> = Power dissipated in a driver when the output changes states ("shoot-through current") in Watts. NOTE: The "shoot-through" current from a dual transition (once up, once down) for both drivers is shown by the "Typical Characteristic Curve : Crossover Area vs. Supply Voltage and is in ampere-seconds. This figure must be multiplied by the number of repetitions per second (frequency) to find Watts.
- R<sub>O</sub> = Output resistance of a driver in Ohms.
- V<sub>S</sub> = Power supply voltage to the IC in Volts.

Figure 6. Peak Output Current Test Circuit
